Chap 6 By St Joseph

Introduction to C

History of C

C is a powerful, portable and elegantly structured programming language. C is an 17 emely popular language because it is simple, efficient, and reliable. 'C' is considered to be a middle-level language since it has the features of both low-level language and high-level language.

The need 5 solve different types of problems on various hardware platforms led to the development of 5 mbined Programming Language(CPL) at Cambridge University in 1963. However, it was too complex, hard to learn and difficult to implement. In 1967, Basic CPL, a 5 bset of CPL, was developed by Martin Richards for writing system software. It inco 1 brated only the essential features of CPL, but it was also not found to be sufficiently powerful. In 1970, Ken Thompson created a language using many features of BCPL and simply called it s 5 ply B. 'B' was to create early versions of UNIX operating systems at Bell Laboratories. In 1972, Dennis Ritchie at AT & T Bell Laboratories developed 'C' language incorporating best features of both BCPL and B languages. It was named as C to present it as the successor of B language.

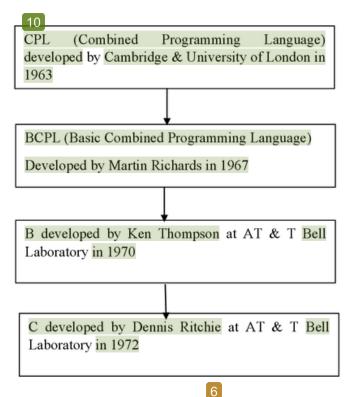

Fig 6.1 Various stages in Evolution of Clanguage

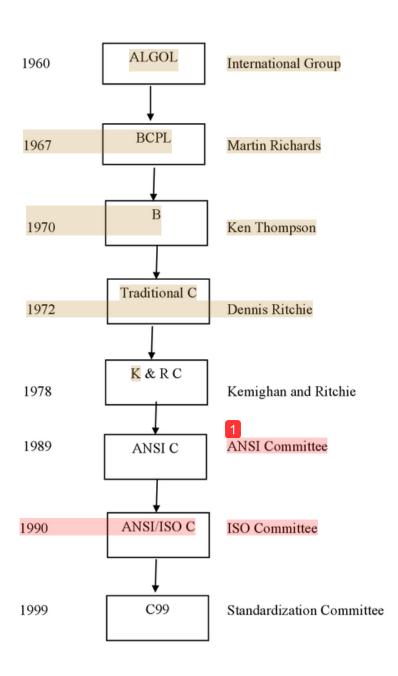

Fig 6.2 History of ANSI C

Features of C Language:

'C' language has been developed for implementing various systems such as 6 erating Systems, Compilers, Linkers, Word Processors and Utility Packages. C language is faster than BASIC language. For example a program to increment a variable from 0 to 15000 takes one second in C while it takes more than 50 seconds in an interpreter of BASIC. There are only 32 keywords in ANSI C and its strength lies in its built-in function.

The various other features of 'C' include the following:

Portable: Portable feature of 'C'states that the 'C' Program written for one computer can be executed on another computer with either little or no modification.

Structured: In 'c", the problem has to be represented in terms of function modules and blocks. The proper collection of these modules would make the complete program. Program debugging, testing, and maintenance become easier because of this modular structure.

Extensible: In 'C' own functions can also be added to the existing 'C' library, which makes it extensible.

Flexible: Clanguage can be used for system programming like UNIX OS, C compiler as well as for application programming.

Robust The rich set of built-in functions and operators that are available in 'C' helps the programmer to write any complex program.

'C' compiler combine 20 e capabilities of an assembly language along with high-level language features. Therefore both system software and business packages can be developed using 'C'.

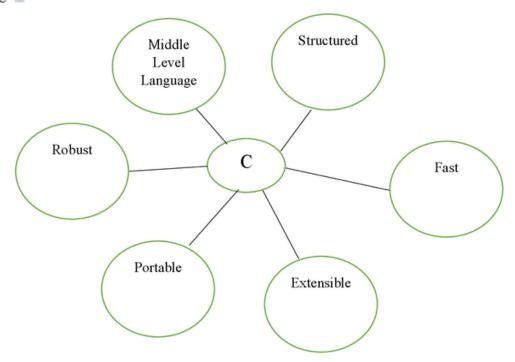

Fig 6.3 Features of C Language

Characteristics of C

- 1. It is a highly structured language.
- It uses features of high level language.
- 3. It can tandle bit-level operations.
- 4. It is a machine -independent language and therefore highly portable.
- 5. It supports a variety of data types and a powerful set of operators.
- 6. It supports dynamic memory management by using the concept of pointers.
- It enables implementation of hierarchical and modular programming with the help of functions
- 8. It can extend itself by addition of functions to its library continuously.

Sample Program 1:

```
main()
{
/*....print.....*/
printf("hai");
/*.....print ends....*/
}
```

In the above program, the first line starts with **main()** which is a special func 18 and it states that the execution begins at this line. Every program 16 that have exactly one main function, else the compiler can't understand the beginning of the program.

The empty pair of parentheses () indicate that the main function has no arguments or parameters. The of thing braces '{'marks the beginning of main function and '}'closing brace marks the end of main function. All the statements between these two braces form the function body. The function body contains a set of instructions to perform the task.

In the above example, function body contains three statements out of the printf line is an executable statement, he comment line /*.....*/ is used to enhance readability and understanding. Comment lines are 141 executable and therefore anything written between it is ignored by the compiler. It can be inserted wherever blank spaces can occur, i.e at the beginning, middle or end of line but never in the middle of the word. Also comment lines can never be nested.

The comment line

/*****.....*/

is not valid and therefore results in an error.

1

The comment line helps in understanding the various functions and operations of a program and serve as an aid in debugging at 2 testing.

In the above example, **printf** is the only executable statement of the program. which is a predefined function for printing output. Predefined function is defined as a function that is already been written and compiled and linked together with the program at the time of linking. The **printf** statement prints out everything that is given between the starting and ending quotation. On executing the above program, the following output will be obtained:

hai

Every statement in C should end with a semi colon. To print in two lines, it should be given as

printf("hai\n"); printff"How are you?");

T 1 information contained between the parenthesis is called the arguments of the function. These arguments are simply strings of characters to 1 printed out.

Newline operator '\n' is used to print in two lines. It instructs the computer to go to the next new line. No space is allowed between \ and n.

Types of main function

C permits different forms of main statement:

1.main()

2. int main ()

In this, function returns an integer value. i.e the last statement in the program must be "return 1"

3. void main ()

The keyword void means that the function does not return any information to the operating system.

Basic structure of C program

C programs can be viewed as a group of building blocks called as functions. A function is a subroutine that may include one or more statements designed to perform a specific task. C program may contain one or more sections as shown in fig below

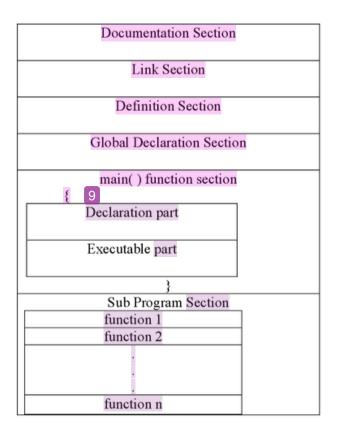

Fig 6.4 An overview of C Program

Documentation Section

This section consists of a set of comment lines giving the name of the program, author and other details.

Link Section

This section provides instruction to the compiler to link functions from the system library.

Definition Section

This section defines all symbolic constants.

Global Declaration Section

Some variables are used in more than one functions. Such variables are called as global variables and are declared in the global declaration that is outside of all functions. All user defined functions are also declared in this section.

main (

Every C program must have one main() function section. This section contains two parts, namely declaration 3 art and executable part. All the variables to be used in the executable part are declared in the declaration 3 t. Executable part contains at least one executable statement. Declaration and Executable parts must appear between the opening and closing braces. The program execution begins at the opening brace and ends at the closing brace. Closing brace of the main function denotes the logical end of the program. All statements in the declaration and executable part must end with semicolon.

Subprogram Section

This section contains all the user defined functions that are called in the main function. User defined functions are generally placed immediately after the main function, although they may appear in any order. All sections except the main function section may be absent, when they are not required.

Programming Style

C programs have to be written in lowercase letters. 4 ppercase letters are used only for symbolic constants. Braces are used to group the statements together and mark the beginning and end of the function. A proper indentation of braces and statements make a program easier to read and debug.

Since C is a free-form language, the statements can be grouped together on one line. For example,

x=y;

x=x+2;

z=x+1:

2

can be written in one line as

$$x=y-x=x+2;z=x+1;$$

However, this style make the program more difficult to understand and should not be used.

Programming Rules:

- All statements must be in lower case letters.
- Blank spaces may be inserted between the words.
- The opening and closing braces must be balanced.
- The statements can be written anywhere between the opening and closing braces.
- 5. Every statement must be terminated by a semicolon (;).

Executing a 'C' Program

- 'C' program is executed in a series of steps which involves the following:
- 1. Creating the program
- 2. Compiling the program
- 3. Linking the program with functions that are needed from the C library and
- Executing the program.

The process of creating, compiling and executing the program is shown in the following figure. The steps for compiling the program remain the same irrespective of the operating system though the system commands for implementing the steps and the convention followed for naming the files may vary on different systems.

1. Creating the program:

13

The program that is to be created is entered into a file. The file name can consist of letters, digits and special characters, followed by the extension .c. Examples of valid file names are:

a.c xyz.c

2. Compiling and Linking:

13

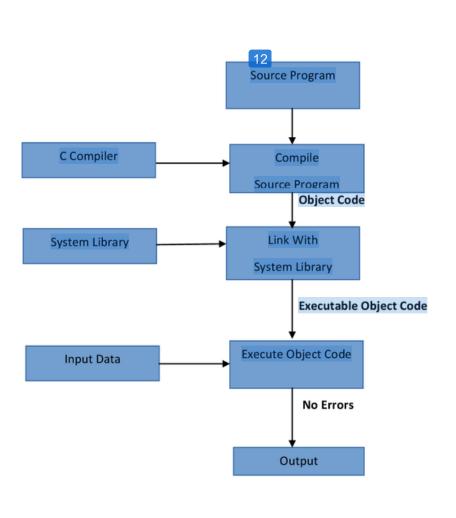

During the compilation process, the source program instructions are translated into a form that is suitable for execution by the computer. The translation process checks each and every instruction for correctness and 7 no errors are reported then it generates the object code. During the linking process, the other program files and functions that are required by the program are put together with it.

During this process, a 8 mistakes in the syntax and semantics of the language are discovered, the errors will be listed out and the compilation process ends here. The errors should be corrected in the source program with the help on an editor and the program is compiled again.

3. Executing the program:

7

During execution, the executable object code is loaded in the computer memory and the instructions will be executed. During execution, the program may request some data through the keyboard.
